

Order-aware LINCS scoring nominates a factorial experiment

A Same profiles, exchanged roles

B The complete scoring rule

$$\begin{aligned}E(e \rightarrow l) &= E(e) + 0.5 E(l) \\M(e \rightarrow l) &= M(e) + 0.5 M(l) \\R(e \rightarrow l) &= R(l) + 0.5 R(e) \\P &= 1.5 \max[0, -\min(E, M)]\end{aligned}$$

$$\begin{aligned}S(e \rightarrow l) &= R + 0.5 E + 0.5 M - P \\A &= S(e \rightarrow l) - S(l \rightarrow e)\end{aligned}$$

The asymmetric early/late coefficients generate the forward-reverse contrast. This score nominates an equal-exposure factorial experiment and provides no observed treatment-order estimate.

C Weight-scheme sensitivity
